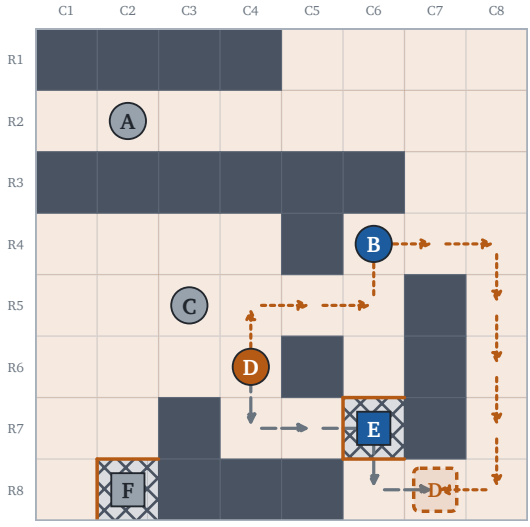
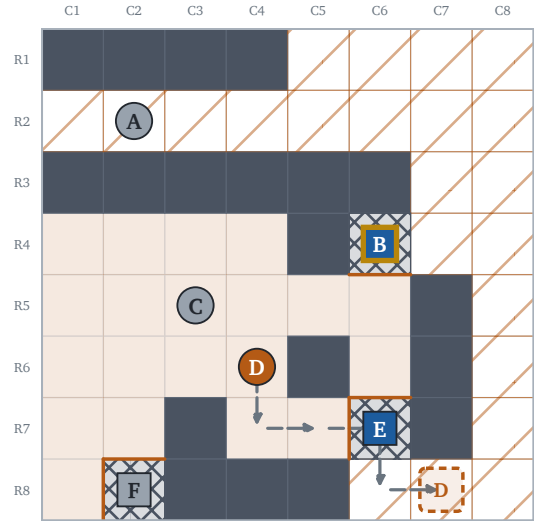
Where no single cell can cut the board, two finished objects can

six players, S4 board 3, Qwen3.8, none — the corridor plays no part in this one

(a) move 46: the southern way round already frozen



(b) move 46: B declares done, closing the northern



object, still able to move
owner declared done: object frozen (square), cell walled
the cut object's target
where the cut object can still move
cells it loses to this declaration
a route that still exists
a route already closed

D must reach R8C7, and the wall block leaves exactly two ways round it: north through R4C6, south through R7C6.

E finished on the southern cell earlier and froze it (long dashes).

B now finishes on the northern one. Both are ordinary target cells, and under masking neither player can see the other's route.

The generator certifies the free space 2-connected, so no single cell severs anything here — and two is all 2-connectedness buys.

31 of the 101 cuts take this form, every one on a board whose minimum vertex cut is 2.

This same pair of targets closed this same board in four independent episodes, two per strong model.
